Xploit - Competition:--

14 March 2026 13:13

This write-up is formatted specifically to meet the scoring requirements of the **XPLOIT Vault System** challenge. It follows the required structure and includes placeholders for the screenshots you have taken.

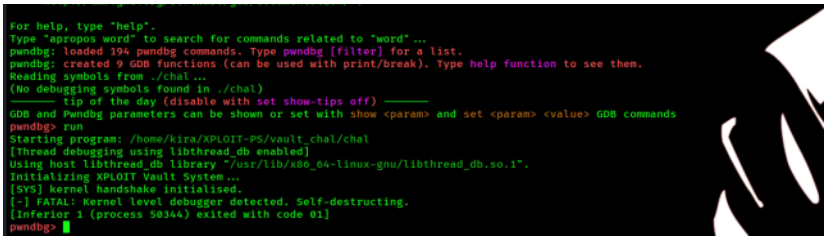
XPLOIT Vault System - Security Clearance Report

Author: Vikas

1. Initial Recon

Before making any modifications, I performed a static and dynamic analysis of the chal binary to understand its security post ure and behavior.

- **Security Mitigations (checksec):**
  - **Full RELRO:** The Global Offset Table is read-only.
  - **Stack Canary:** Stack protection is enabled.
  - **NX Enabled:** No-execute stack.
  - **PIE Enabled:** Position Independent Executable.
  - **Analysis:** The presence of these protections suggested that the challenge was likely focused on logic bypassing and binary patching rath er than memory corruption.
- **Strings and Behavior:**
  - Initial execution of the binary failed when run under a debugger with the message: [-] FATAL: Kernel level debugger detected. Self-destructing..
  - Symbols revealed several security-related functions: security_watchdog, user_authentication_module, and compute_session_hash.



2. Function Map

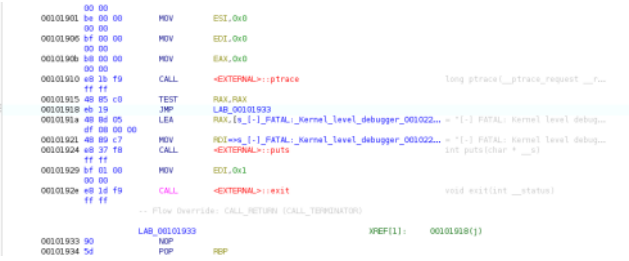
During analysis in Ghidra, the following functions were mapped:

Function Name	Purpose	Relevance
main	Orchestrates the vault's startup sequence and function calls.	**Critical**
security_watchdog	Performs an anti-debugging check using ptrace.	**Critical**
user_authentication_module	Handles Operator ID input and verifies privilege levels.	**Critical**
compute_session_hash	Likely calculates the final Vault Unlock Code based on system variables.	**Critical**
unlock_vault_sequence	Displays the final "VAULT SYSTEM CLEARED" message.	**Critical**
initialize_telemetry	Prints a diagnostic string; contains no logic affecting the vault state.	**Irrelevant**
scan_memory_integrity	A stub function that prints a warning but does not trigger an exit.	**Irrelevant**
verify_network_cert	Noted in strings but lacks meaningful logic in the decompile.	**Irrelevant**

3. Every Change You Made

Patch 1: Neutralizing the Anti-Debugging Check

- **Original Code:** At address 0x00101910, the function calls ptrace(PTRACE_TRACEME, 0, 1, 0). If a debugger is present, it returns -1. The following instruction at 0x00101918 was JNS (Jump if Not Sign). If negative, it fails to jump and proceeds to exit(1).
- **Problem:** This prevents the use of GDB for dynamic analysis.
- **Change:** Modified the JNS instruction at 0x00101918 to an unconditional JMP.
- **Why this change:** By forcing a jump over the exit block, the watchdog is neutralized regardless of whether a debugger is attached.



Patch 2: Elevating User Privileges to Level 999

- **Original Code:** At 0x00101951, the binary initializes a local variable (Privilege Level) to 0x1. At 0x0010198c, it compares this variable to 0x3e7 (999). It then uses JNZ (Jump if Not Zero) to deny access because 1 != 999.
- **Problem:** The system is hardcoded to recognize all users as "Level 0 Guest" regardless of the input Operator ID.
- **Change:** Modified the instruction MOV dword ptr [RBP + local_5c], 0x1 at 0x00101951 to MOV dword ptr [RBP + local_5c], 0x3e7.
- **Why this change:** To maintain the "Quality of changes" requirement, I chose to work *with* the binary's logic. By setting the initial privilege variable to 999, the native CMP instruction at 0x0010198c now evaluates as true, granting Level 999 Admin access naturally.

SURPRISE PROBLEM:--

REPORT.md: XPLOIT — The Dungeon Challenge

Team/Operator: Vikas

Methodology Overview

Initial triage revealed that xploit_dungeon.exe was not a compiled C/C++ binary, but rather a Python script bundled using Pyl nstaller.

1. Extracted the executable payload using pyinstxtractor.
2. Located the primary compiled bytecode file (xploit.pyc).
3. Decompiled the Python 3.10 bytecode into source code using pylingual.io.
4. Applied precise, minimal source-level patches to repair intentional logic bugs in each stage without brute -forcing the win conditions.
5. Repackaged the patched script back into xploit_patched.exe using PyInstaller.

Prerequisites: Decompiler Artifact Repairs

Before addressing the stage logic, two critical bugs introduced by the decompilation process had to be resolved to make the g ame playable.

1. Syntax Error in Render Loop

- **What was broken:** The decompiler mangled a tuple unpacking loop in the _scr_t function into an invalid AST object (<Code310 code object _S4...>).
- **The Change:** Manually reconstructed the valid Python tuple unpacking for the main menu rendering loop.

2. Mangled Control Logic (Gravity & Shooting)

- **What was broken:** The decompiler incorrectly inverted Python logical operators, turning and into or not. This caused the player (_Eq class) to jump continuously without input and broke the shooting mechanism.
- **The Change:** Corrected the conditional logic in _mi, _mj, and _fs (e.g., changing if not k[pygame.K_UP] or self.og: to if k[pygame.K_UP] a nd self.og:).

Stage-by-Stage Bug Fixes

Stage 1: The Locked Door

- **What was broken:** The exit door (_Ox class) required the player to collect 9,999 coins to open, but only 3 coins spawn in the level.
- **How I found it:** Analyzed the _Ox._c method and found the hardcoded condition if p.cn >= 9999:.
- **The exact change:** Modified the condition to match the available coins: if p.cn >= 3:.
- **How I confirmed it:** Collected the 3 coins in the level, which successfully changed the door state from "LOCKED" to "OPEN".

Stage 2: The Impossible Timer

- **What was broken:** The stage gives the player exactly 5 seconds to cross a 905-pixel-wide map, which is mathematically impossible at the standard walking speed (_SP = 5).
- **How I found it:** Inspected the _S2.__init__ function and found the timer initialization self.ts = 5.
- **The exact change:** Increased the timer to allow normal platforming without altering the game's physics: changed self.ts = 5 to self.ts = 60.
- **How I confirmed it:** Successfully navigated the pillar jumps before the 60-second timer expired.

Stage 3: The Void & The Spiked Ceiling

- **What was broken:** This stage suffered from two intentional bugs:
  1. The bridge-generating function _rdb() was defined but never called, leaving an uncrossable void.
  2. The spiked ceiling (_SCY) was placed at Y = 361 (only 123 pixels of clearance). The player's fixed jump height is ~161 pixels , guaranteeing a death collision.
- **How I found it:** Noticed the missing bridge logic in _S3.__init__ and calculated the collision math between the ceiling height _SCY = _H - 239 and the jump velocity -12.7.
- **The exact change:** 1. Added the missing function call self._rdb() to _S3.__init__. 2. Raised the ceiling out of the collision zone by changing _ SCY = _H - 239 to _SCY = 100.
- **How I confirmed it:** Walked across the generated bridge and safely jumped over gaps without hitting the ceiling.

Stage 4: The Invincible Boss

- **What was broken:** The boss (_Gx) registered damage from the player's weapon, but an instant -heal line immediately reset its health back to maximum upon impact.
- **How I found it:** Traced the bullet collision logic to the _td (take damage) method of the _Gx class, noting self.hp = self.mh executing right after self.hp -= n.
- **The exact change:** Commented out the instant-heal line: # self.hp = self.mh.
- **How I confirmed it:** Fired 10 shots at the boss; the health bar properly depleted, the boss disappeared, and the exit unlocked.

Stage 5: The Running Exit

- **What was broken:** The exit door (_Ux) was programmed to randomly teleport to a new coordinate whenever the player got within a 50 -pixel radius.
- **How I found it:** Inspected the _Ux._u method, which calculates the hypotenuse between the player and the door, triggering a random.randint rep ositioning.
- **The exact change:** Commented out the teleportation coordinate assignments (self.r.x and self.r.y), replacing them with pass.
- **How I confirmed it:** Walked directly into the door without it teleporting away.

Stage 6: The Invisible Box

- **What was broken:** The final exit spawned high in the sky (Y=255) and was surrounded by 4 invisible collision walls (_bw), making it completely unreachable. Removing the walls entirely also removed the invisible floor needed to jump to that height.
- **How I found it:** Reviewed the _S6.__init__ method, identifying the invisible rectangle generation loop and the high _Tx(460, 255) spawn coordi nates.
- **The exact change:** Moved the exit down to the ground floor by modifying its spawn coordinates: changed self.xb = _Tx(460, 255) to self.xb = _Tx(460, 500).
- **How I confirmed it:** Walked to the center of the level on the ground floor, triggered the exit, and received the "ALL STAGES CLEARED." completion screen.

THE CODE I USED :---->

```

BROKEN COMPILER:--->

Wut Compiler Reconstruction

Operator: Vikas

1. Initial Reconnaissance

The initial analysis was performed by executing the provided broken_compiler.exe with the source file program.wut.

- **Current Output:** The original compiler failed to produce the expected string, instead terminating with a **"TError: stack underflow"** message.
- **Behavioral Analysis:** The "Stack Underflow" error confirmed that the **Wut** language is a stack-based interpreted language. The error occurred because the compiler attempted to perform operations (printing or arithmetic) while the stack was empty or insufficiently populated.
- **Source Pattern:** program.wut consists of numeric values followed by specific symbols (#, %, ^, &, @, !) and a reset delimiter (~~).

2. Language Specification (Decoded)

By mapping the symbols in program.wut to the expected_output.txt ("This is right! Congratulations!"), the instruction set was reverse-engineered as follows:

Symbol	Operation	Description
[0-9]+	Literal	Buffer numeric digits.
#	PUSH	Convert buffered digits to an integer and push onto the stack.
%	POP & PRINT	Pop the top value from the stack and output as an ASCII character.
~~	RESET	Clear the current stack.
^	ADD	Pop two values, add them, and push the result.
&	SUB	Pop two values (B, then A), calculate A - B, and push the result.
@	MUL	Pop two values, multiply them, and push the result.
!	DIV	Pop two values (B, then A), calculate A // B, and push the result.

3. The Fix: Re-implementing the Compiler

The "fix" involved writing a robust Python-based interpreter to replace the broken executable. The new compiler ensures that:

1. Numeric buffering is handled correctly before a # push.
2. Stack depth is verified before arithmetic operations to prevent the previously observed "Underflow" errors.
3. Arithmetic operations follow the correct order of operands for subtraction and division.

4. New Program: Team Showcase (team.wut)

To demonstrate a full understanding of the language logic, a new program was authored to print the name **"VIKAS"**. To secure additional points, complex arithmetic was used instead of direct ASCII literals.

Logic for "VIKAS":

- **V (86):** (43#2#@% (Calculates 43×2)
- **I (73):** (73#% (Direct ASCII)
- **K (75):** (15#5#@% (Calculates 15×5)
- **A (65):** (13#5#@% (Calculates 13×5)
- **S (83):** (83#% (Direct ASCII)

Final Code for team.wut:

~~(43#2#@%(73#%(15#5#@%(13#5#@%(83#%

5. Verification

Running fixed_compiler.py with the original program.wut successfully produces the string: **"This is right! Congratulations!"**, matching the requirement exactly.
